Deployment Pipeline

Deployment Pipeline (Textual) - LawVriksh Credits Service

Environments: dev, staging, prod. Git default branch 'main', protected. Feature branches via PRs, code review, CI checks required.

CI (GitHub Actions): lint (ruff/black), type-check (pyright), unit tests (pytest), build docker image, run integration tests against ephemeral Postgres container applying schema.sql, export Postman tests via newman.

Image Registry: push versioned image 'lawvriksh/credits:<git-sha>' and 'latest' on main.

CD (Render/Railway/Cloud Run): staging auto-deploy on 'main'; prod deploy via manual approval. Migrations applied on startup using schema.sql, plus API-driven migrations as needed.

Secrets: managed via platform secret store. ADMIN_API_KEY and DATABASE_URL injected as env vars.

Observability: health endpoint /healthz, logs centralized, metrics (request rate/error rate) via platform. Uptime monitor pings /healthz.

Scheduler: daily credit update via APScheduler in app or platform cron at 00:00 UTC executing SQL UPDATE. Single-run lock achieved by running one instance of scheduled job.

Rollback: Deploy previous image tag; database changes via migration table audit; avoid destructive changes without backup.

Backups: automated daily backups of Postgres with 7/30 retention depending on environment.
